Database: Warehouse Goods Database

Purpose

To create a centralized Warehouse Management System to track inventory levels across multiple storage facilities, manage product details, categorize items, and monitor supplier information for purchasing and supply chain operations.

Explaination:

This database is structured into five normalized tables to manage a warehouse system efficiently. The Categories and Suppliers tables organize product types and vendor details, which link to the master Products catalog via one-to-many relationships.

Meanwhile, the Warehouses table tracks physical storage locations. To handle the real-world scenario where one product can be stored in many warehouses and one warehouse stores many products (a *Many-to-Many* relationship), we use the Stock_Inventory table as a bridge or junction table. This splits the complex Many-to-Many connection into two clean One-to-Many relationships, allowing the database to accurately monitor exact stock quantities and reorder limits across different facilities.
